

# Deep Learning

Lecture 2: Multi-layer perceptron

Prof. Gilles Louppe  
[g.louppe@uliege.be](mailto:g.louppe@uliege.be)

# Today

Explain and motivate the basic constructs of neural networks.

- From linear discriminant analysis to logistic regression
- Stochastic gradient descent
- From logistic regression to the multi-layer perceptron
- Vanishing gradients and rectified networks
- Universal approximation theorem

# Neural networks

# Perceptron

The Mark I Perceptron (Rosenblatt, 1960) is one of the earliest instances of a neural network.

Figure 1 ORGANIZATION OF THE MARK I PERCEPTRON

The Mark I Percetron was implemented in hardware.

The machine could classify simple images.

The Mark I Perceptron is composed of association and response units (or "perceptrons"), each acting as a binary classifier that computes a linear combination of its inputs and applies a step function to the result.

In the modern sense, given an input  $\mathbf{x} \in \mathbb{R}^p$ , each unit computes its output as

$$f(\mathbf{x}) = \begin{cases} 1 & \text{if } \sum_i w_i x_i + b \geq 0 \\ 0 & \text{otherwise} \end{cases}$$

The classification rule can be rewritten as

$$f(\mathbf{x}) = \text{sign}\left(\sum_i w_i x_i + b\right)$$

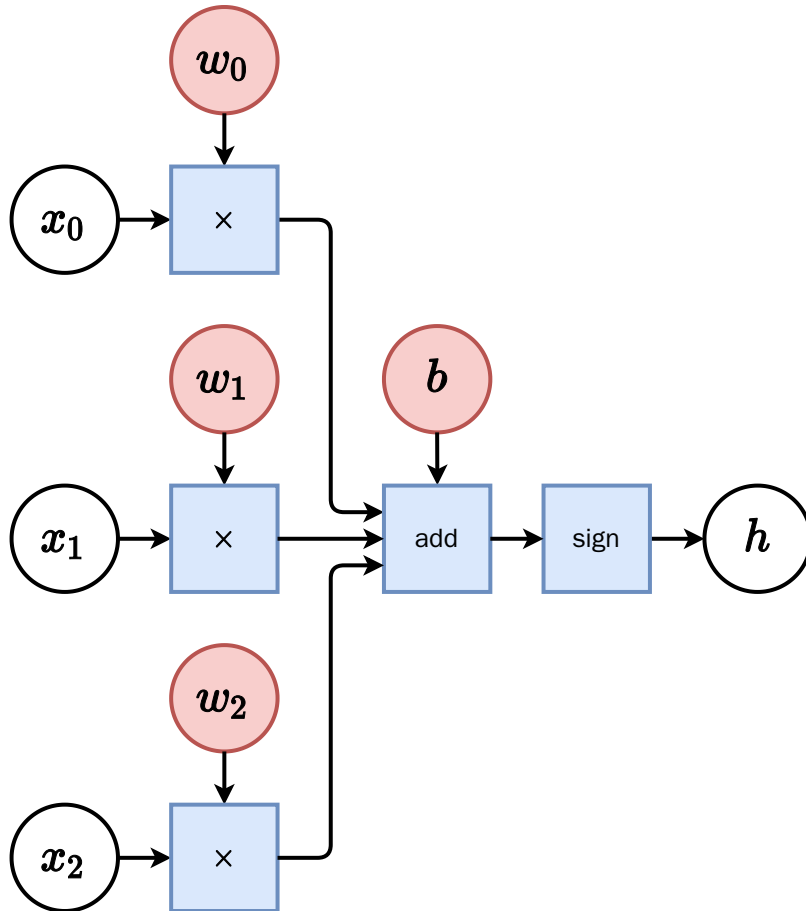

where  $\text{sign}(x)$  is the non-linear **activation** function

$$\text{sign}(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ 0 & \text{otherwise} \end{cases}$$

## Computational graphs

The computation of

$$f(\mathbf{x}) = \text{sign}\left(\sum_i w_i x_i + b\right)$$

can be represented as a **computational graph** where

- white nodes correspond to inputs and outputs;
- red nodes correspond to model parameters;
- blue nodes correspond to intermediate operations.

In terms of **tensor operations**,  $f$  can be rewritten as

$$f(\mathbf{x}) = \text{sign}(\mathbf{w}^T \mathbf{x} + b),$$

for which the corresponding computational graph of  $f$  is:

# Linear discriminant analysis

Consider training data  $(\mathbf{x}, y) \sim p_{X,Y}$ , with

- $\mathbf{x} \in \mathbb{R}^p$ ,
- $y \in \{0, 1\}$ .

Assume class populations are Gaussian, with same covariance matrix  $\Sigma$  (homoscedasticity):

$$p(\mathbf{x}|y) = \frac{1}{\sqrt{(2\pi)^p |\Sigma|}} \exp\left(-\frac{1}{2}(\mathbf{x} - \mu_y)^T \Sigma^{-1}(\mathbf{x} - \mu_y)\right)$$

Using the Bayes' rule, we have:

$$\begin{aligned} p(y = 1|\mathbf{x}) &= \frac{p(\mathbf{x}|y = 1)p(y = 1)}{p(\mathbf{x})} \\ &= \frac{p(\mathbf{x}|y = 1)p(y = 1)}{p(\mathbf{x}|y = 0)p(y = 0) + p(\mathbf{x}|y = 1)p(y = 1)} \\ &= \frac{1}{1 + \frac{p(\mathbf{x}|y=0)p(y=0)}{p(\mathbf{x}|y=1)p(y=1)}}. \end{aligned}$$

Using the Bayes' rule, we have:

$$\begin{aligned} p(y = 1|\mathbf{x}) &= \frac{p(\mathbf{x}|y = 1)p(y = 1)}{p(\mathbf{x})} \\ &= \frac{p(\mathbf{x}|y = 1)p(y = 1)}{p(\mathbf{x}|y = 0)p(y = 0) + p(\mathbf{x}|y = 1)p(y = 1)} \\ &= \frac{1}{1 + \frac{p(\mathbf{x}|y=0)p(y=0)}{p(\mathbf{x}|y=1)p(y=1)}}. \end{aligned}$$

It follows that with

$$\sigma(x) = \frac{1}{1 + \exp(-x)},$$

we get

$$p(y = 1|\mathbf{x}) = \sigma \left( \log \frac{p(\mathbf{x}|y = 1)}{p(\mathbf{x}|y = 0)} + \log \frac{p(y = 1)}{p(y = 0)} \right).$$

Therefore,

$$\begin{aligned} p(y = 1|\mathbf{x}) &= \sigma \left( \log \frac{p(\mathbf{x}|y = 1)}{p(\mathbf{x}|y = 0)} + \underbrace{\log \frac{p(y = 1)}{p(y = 0)}}_a \right) \\ &= \sigma (\log p(\mathbf{x}|y = 1) - \log p(\mathbf{x}|y = 0) + a) \\ &= \sigma \left( -\frac{1}{2}(\mathbf{x} - \mu_1)^T \Sigma^{-1} (\mathbf{x} - \mu_1) + \frac{1}{2}(\mathbf{x} - \mu_0)^T \Sigma^{-1} (\mathbf{x} - \mu_0) + a \right) \\ &= \sigma \left( \underbrace{(\mu_1 - \mu_0)^T \Sigma^{-1} \mathbf{x}}_{\mathbf{w}^T} + \underbrace{\frac{1}{2}(\mu_0^T \Sigma^{-1} \mu_0 - \mu_1^T \Sigma^{-1} \mu_1)}_b + a \right) \\ &= \sigma (\mathbf{w}^T \mathbf{x} + b) \end{aligned}$$

Note that the **sigmoid** function

$$\sigma(x) = \frac{1}{1 + \exp(-x)}$$

looks like a soft heavyside:

Therefore, the overall model  $f(\mathbf{x}; \mathbf{w}, b) = \sigma(\mathbf{w}^T \mathbf{x} + b)$  is very similar to the perceptron.

This unit is the main **primitive** of all neural networks!

# Logistic regression

Same model

$$p(y = 1|\mathbf{x}) = \sigma(\mathbf{w}^T \mathbf{x} + b)$$

as for linear discriminant analysis.

But,

- **ignore** model assumptions (Gaussian class populations, homoscedasticity);
- instead, find  $\mathbf{w}, b$  that maximizes the likelihood of the data.

We have,

$$\begin{aligned} & \arg \max_{\mathbf{w}, b} p(\mathbf{d} | \mathbf{w}, b) \\ &= \arg \max_{\mathbf{w}, b} \prod_{\mathbf{x}_i, y_i \in \mathbf{d}} p(y = y_i | \mathbf{x}_i, \mathbf{w}, b) \\ &= \arg \max_{\mathbf{w}, b} \prod_{\mathbf{x}_i, y_i \in \mathbf{d}} \sigma(\mathbf{w}^T \mathbf{x}_i + b)^{y_i} (1 - \sigma(\mathbf{w}^T \mathbf{x}_i + b))^{1-y_i} \\ &= \arg \min_{\mathbf{w}, b} \underbrace{\sum_{\mathbf{x}_i, y_i \in \mathbf{d}} -y_i \log \sigma(\mathbf{w}^T \mathbf{x}_i + b) - (1 - y_i) \log(1 - \sigma(\mathbf{w}^T \mathbf{x}_i + b))}_{\mathcal{L}(\mathbf{w}, b) = \sum_i \ell(y_i, \hat{y}(\mathbf{x}_i; \mathbf{w}, b))} \end{aligned}$$

This loss is an instance of the **cross-entropy**

$$H(p, q) = \mathbb{E}_p[-\log q]$$

for  $p = p_{Y|\mathbf{x}_i}$  and  $q = p_{\hat{Y}|\mathbf{x}_i}$ .

# Multi-layer perceptron

So far we considered the logistic unit  $h = \sigma(\mathbf{w}^T \mathbf{x} + b)$ , where  $h \in \mathbb{R}$ ,  $\mathbf{x} \in \mathbb{R}^p$ ,  $\mathbf{w} \in \mathbb{R}^p$  and  $b \in \mathbb{R}$ .

These units can be composed in parallel to form a layer with  $q$  outputs:

$$\mathbf{h} = \sigma(\mathbf{W}^T \mathbf{x} + \mathbf{b})$$

where  $\mathbf{h} \in \mathbb{R}^q$ ,  $\mathbf{x} \in \mathbb{R}^p$ ,  $\mathbf{W} \in \mathbb{R}^{p \times q}$ ,  $\mathbf{b} \in \mathbb{R}^q$  and where  $\sigma(\cdot)$  is upgraded to the element-wise sigmoid function.

Similarly, layers can be composed **in series**, such that:

$$\begin{aligned}\mathbf{h}_0 &= \mathbf{x} \\ \mathbf{h}_1 &= \sigma(\mathbf{W}_1^T \mathbf{h}_0 + \mathbf{b}_1) \\ &\dots \\ \mathbf{h}_L &= \sigma(\mathbf{W}_L^T \mathbf{h}_{L-1} + \mathbf{b}_L) \\ f(\mathbf{x}; \theta) &= \hat{y} = \mathbf{h}_L\end{aligned}$$

where  $\theta$  denotes the model parameters  $\{\mathbf{W}_k, \mathbf{b}_k, \dots | k = 1, \dots, L\}$ .

This model is the **multi-layer perceptron**, also known as the fully connected feedforward network.

## Output layers

- For binary classification, the width  $q$  of the last layer  $L$  is set to  $1$  and the activation function is the sigmoid  $\sigma(\cdot) = \frac{1}{1+\exp(-\cdot)}$ , which results in a single output  $h_L \in [0, 1]$  that models the probability  $p(y = 1|\mathbf{x})$ .
- For multi-class classification, the sigmoid activation  $\sigma$  in the last layer can be generalized to produce a vector  $\mathbf{h}_L \in \Delta^C$  of probability estimates  $p(y = i|\mathbf{x})$ . This activation is the **Softmax** function, where its  $i$ -th output is defined as

$$\text{Softmax}(\mathbf{z})_i = \frac{\exp(z_i)}{\sum_{j=1}^C \exp(z_j)},$$

for  $i = 1, \dots, C$ .

- For regression, the width  $q$  of the last layer  $L$  is set to the dimensionality of the output  $d_{\text{out}}$  and the activation function is the identity  $\sigma(\cdot) = \cdot$ , which results in a vector  $\mathbf{h}_L \in \mathbb{R}^{d_{\text{out}}}$ .

(demo)

## Expressiveness

Let us consider the 1-hidden layer MLP

$$f(x) = \sum w_i \text{sign}(x + b_i).$$

This model can approximate any smooth 1D function to arbitrary precision, provided enough hidden units.

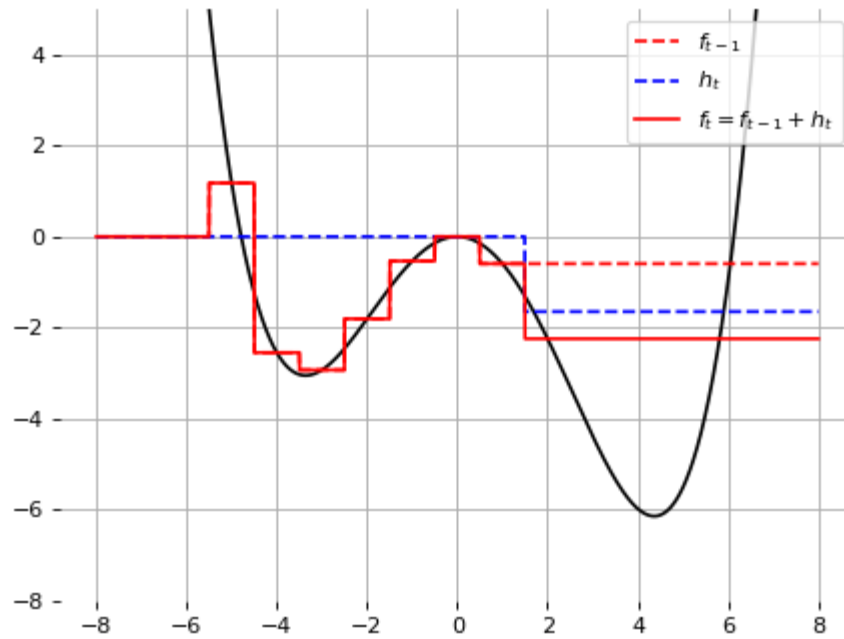

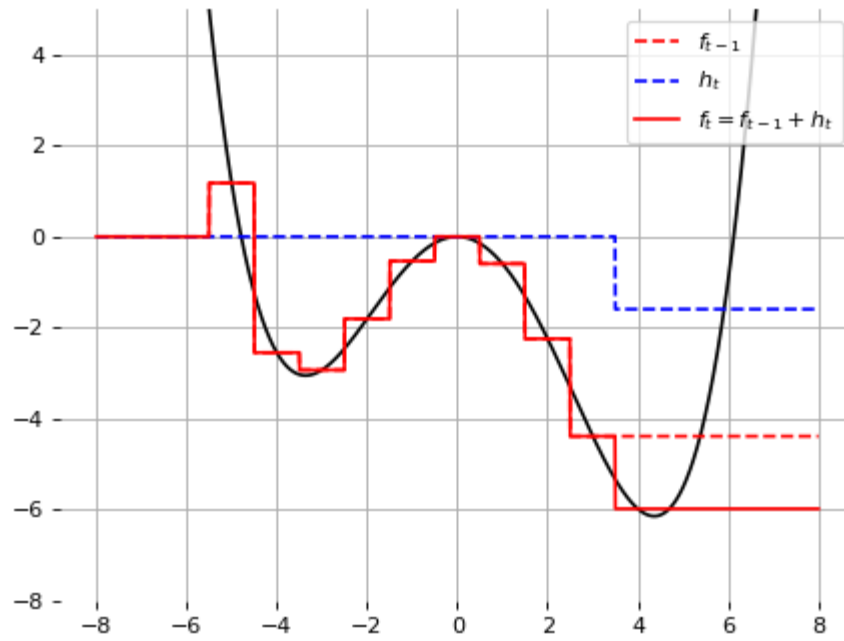

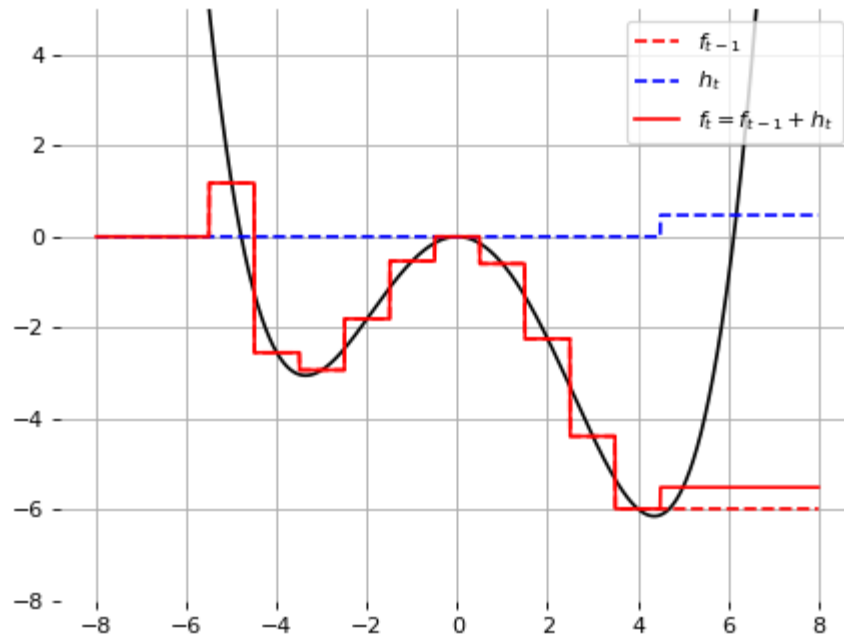

**Universal approximation theorem.** (Cybenko 1989; Hornik et al, 1991) Let  $\sigma(\cdot)$  be a bounded, non-constant continuous function. Let  $I_p$  denote the  $p$ -dimensional hypercube, and  $C(I_p)$  denote the space of continuous functions on  $I_p$ . Given any  $f \in C(I_p)$  and  $\epsilon > 0$ , there exists  $q > 0$  and  $v_i, w_i, b_i, i = 1, \dots, q$  such that

$$F(x) = \sum_{i \leq q} v_i \sigma(w_i^T x + b_i)$$

satisfies

$$\sup_{x \in I_p} |f(x) - F(x)| < \epsilon.$$

- It guarantees that even a single hidden-layer network can represent any classification problem in which the boundary is locally linear (smooth);
- It does not inform about good/bad architectures, nor how they relate to the optimization procedure.
- The universal approximation theorem generalizes to any non-polynomial (possibly unbounded) activation function, including the ReLU (Leshno, 1993).

# Training

# Loss functions

The parameters (e.g.,  $\mathbf{W}_k$  and  $\mathbf{b}_k$  for each layer  $k$ ) of an MLP  $f(\mathbf{x}; \theta)$  are learned by minimizing a loss function  $\mathcal{L}(\theta)$  over a dataset  $\mathbf{d} = \{(\mathbf{x}_j, \mathbf{y}_j)\}$  of input-output pairs.

The loss function is derived from the likelihood:

- For classification, assuming a categorical likelihood, the loss is the cross-entropy  $\mathcal{L}(\theta) = -\frac{1}{N} \sum_{(\mathbf{x}_j, \mathbf{y}_j) \in \mathbf{d}} \sum_{i=1}^C y_{ji} \log f_i(\mathbf{x}_j; \theta)$ .
- For regression, assuming a Gaussian likelihood, the loss is the mean squared error  $\mathcal{L}(\theta) = \frac{1}{N} \sum_{(\mathbf{x}_j, \mathbf{y}_j) \in \mathbf{d}} (\mathbf{y}_j - f(\mathbf{x}_j; \theta))^2$ .

# Gradient descent

To minimize  $\mathcal{L}(\theta)$ , **gradient descent** uses local linear information to iteratively move towards a (local) minimum.

For  $\theta_0 \in \mathbb{R}^d$ , a first-order approximation around  $\theta_0$  can be defined as

$$\hat{\mathcal{L}}(\epsilon; \theta_0) = \mathcal{L}(\theta_0) + \epsilon^T \nabla_{\theta} \mathcal{L}(\theta_0) + \frac{1}{2\gamma} \|\epsilon\|^2.$$

A minimizer of the approximation  $\hat{\mathcal{L}}(\epsilon; \theta_0)$  is given for

$$\begin{aligned}\nabla_{\epsilon} \hat{\mathcal{L}}(\epsilon; \theta_0) &= 0 \\ &= \nabla_{\theta} \mathcal{L}(\theta_0) + \frac{1}{\gamma} \epsilon,\end{aligned}$$

which results in the best improvement for the step  $\epsilon = -\gamma \nabla_{\theta} \mathcal{L}(\theta_0)$ .

Therefore, model parameters can be updated iteratively using the update rule

$$\theta_{t+1} = \theta_t - \gamma \nabla_{\theta} \mathcal{L}(\theta_t),$$

where

- $\theta_0$  are the initial parameters of the model;
- $\gamma$  is the **learning rate**;
- both are critical for the convergence of the update rule.

## Stochastic gradient descent

In the empirical risk minimization setup,  $\mathcal{L}(\theta)$  and its gradient decompose as

$$\mathcal{L}(\theta) = \frac{1}{N} \sum_{\mathbf{x}_i, y_i \in \mathbf{d}} \ell(y_i, f(\mathbf{x}_i; \theta))$$
$$\nabla \mathcal{L}(\theta) = \frac{1}{N} \sum_{\mathbf{x}_i, y_i \in \mathbf{d}} \nabla \ell(y_i, f(\mathbf{x}_i; \theta)).$$

Therefore, in **batch** gradient descent the complexity of an update grows linearly with the size  $N$  of the dataset. This is bad!

Since the empirical risk is already an approximation of the expected risk, it should not be necessary to carry out the minimization with great accuracy.

Instead, **stochastic** gradient descent uses as update rule:

$$\theta_{t+1} = \theta_t - \gamma \nabla \ell(y_{i(t+1)}, f(\mathbf{x}_{i(t+1)}; \theta_t))$$

- Iteration complexity is independent of  $N$ .
- The stochastic process  $\{\theta_t | t = 1, \dots\}$  depends on the examples  $i(t)$  picked randomly at each iteration.

Instead, **stochastic** gradient descent uses as update rule:

$$\theta_{t+1} = \theta_t - \gamma \nabla \ell(y_{i(t+1)}, f(\mathbf{x}_{i(t+1)}; \theta_t))$$

- Iteration complexity is independent of  $N$ .
- The stochastic process  $\{\theta_t | t = 1, \dots\}$  depends on the examples  $i(t)$  picked randomly at each iteration.

*Batch gradient descent*

*Stochastic gradient descent*

Why is stochastic gradient descent still a good idea?

- Informally, averaging the update

$$\theta_{t+1} = \theta_t - \gamma \nabla \ell(y_{i(t+1)}, f(\mathbf{x}_{i(t+1)}; \theta_t))$$

over all choices  $i(t+1)$  restores batch gradient descent.

- Formally, if the gradient estimate is **unbiased**, that is, if

$$\begin{aligned} \mathbb{E}_{i(t+1)} [\nabla \ell(y_{i(t+1)}, f(\mathbf{x}_{i(t+1)}; \theta_t))] &= \frac{1}{N} \sum_{\mathbf{x}_i, y_i \in \mathbf{d}} \nabla \ell(y_i, f(\mathbf{x}_i; \theta_t)) \\ &= \nabla \mathcal{L}(\theta_t) \end{aligned}$$

then the formal convergence of SGD can be proved, under appropriate assumptions.

- If training is limited to a single pass over the data, then SGD directly minimizes the **expected** risk.

The excess error characterizes the expected risk discrepancy between the Bayes model and the approximate empirical risk minimizer. It can be decomposed as

$$\begin{aligned} & \mathbb{E} \left[ R(\tilde{f}_*^{\mathbf{d}}) - R(f_B) \right] \\ &= \mathbb{E} \left[ R(f_*) - R(f_B) \right] + \mathbb{E} \left[ R(f_*^{\mathbf{d}}) - R(f_*) \right] + \mathbb{E} \left[ R(\tilde{f}_*^{\mathbf{d}}) - R(f_*^{\mathbf{d}}) \right] \\ &= \mathcal{E}_{\text{app}} + \mathcal{E}_{\text{est}} + \mathcal{E}_{\text{opt}} \end{aligned}$$

where

- $\mathcal{E}_{\text{app}}$  is the approximation error due to the choice of an hypothesis space,
- $\mathcal{E}_{\text{est}}$  is the estimation error due to the empirical risk minimization principle,
- $\mathcal{E}_{\text{opt}}$  is the optimization error due to the approximate optimization algorithm.

A fundamental result due to Bottou and Bousquet (2011) states that stochastic optimization algorithms (e.g., SGD) yield strong generalization performance (in terms of excess error) despite being poor optimization algorithms for minimizing the empirical risk.

# Automatic differentiation (teaser)

To minimize  $\mathcal{L}(\theta)$  with stochastic gradient descent, we need the gradient

$$\nabla \ell(\theta) = \begin{bmatrix} \frac{\partial \ell}{\partial \theta_0}(\theta) \\ \vdots \\ \frac{\partial \ell}{\partial \theta_{K-1}}(\theta) \end{bmatrix}$$

i.e., a vector that gathers the partial derivatives of the loss for each model parameter  $\theta_k$  for  $k = 0, \dots, K - 1$ .

These derivatives can be evaluated automatically from the [computational graph](#) of  $\ell$  using [automatic differentiation](#).

## Backpropagation

- In Leibniz notations, the **chain rule** states that

$$\frac{\partial \ell}{\partial \theta_i} = \sum_{k \in \text{parents}(\ell)} \frac{\partial \ell}{\partial u_k} \underbrace{\frac{\partial u_k}{\partial \theta_i}}_{\text{recursive case}}$$

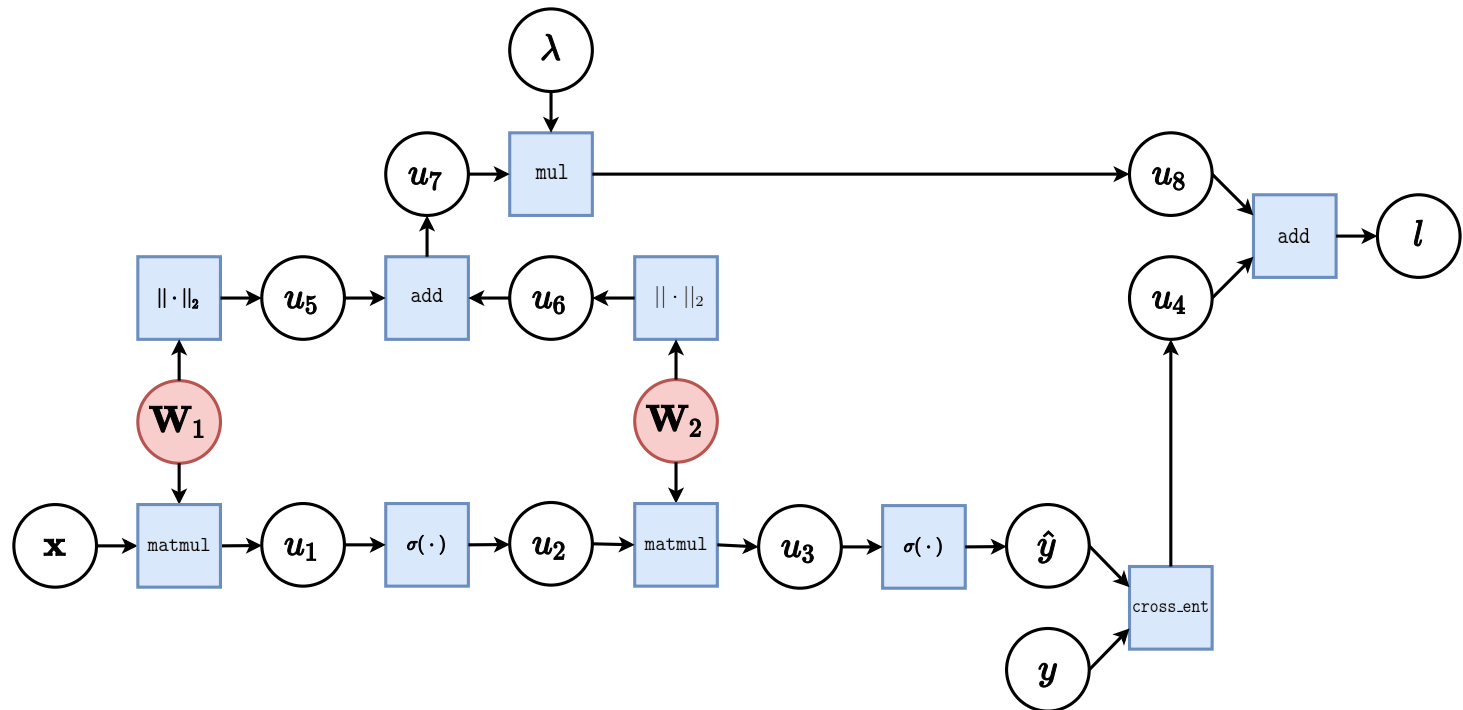

- Since a neural network is a **composition of differentiable functions**, the total derivatives of the loss can be evaluated backward, by applying the chain rule recursively over its computational graph.
- The implementation of this procedure is called reverse **automatic differentiation** (or backpropagation in the context of neural networks).

Let us consider a simplified 1-hidden layer MLP and the following loss function:

$$f(\mathbf{x}; \mathbf{W}_1, \mathbf{W}_2) = \sigma(\mathbf{W}_2^T \sigma(\mathbf{W}_1^T \mathbf{x}))$$
$$\ell(y, \hat{y}; \mathbf{W}_1, \mathbf{W}_2) = \text{cross\_ent}(y, \hat{y}) + \lambda (\|\mathbf{W}_1\|_2 + \|\mathbf{W}_2\|_2)$$

for  $\mathbf{x} \in \mathbb{R}^p$ ,  $y \in \mathbb{R}$ ,  $\mathbf{W}_1 \in \mathbb{R}^{p \times q}$  and  $\mathbf{W}_2 \in \mathbb{R}^q$ .

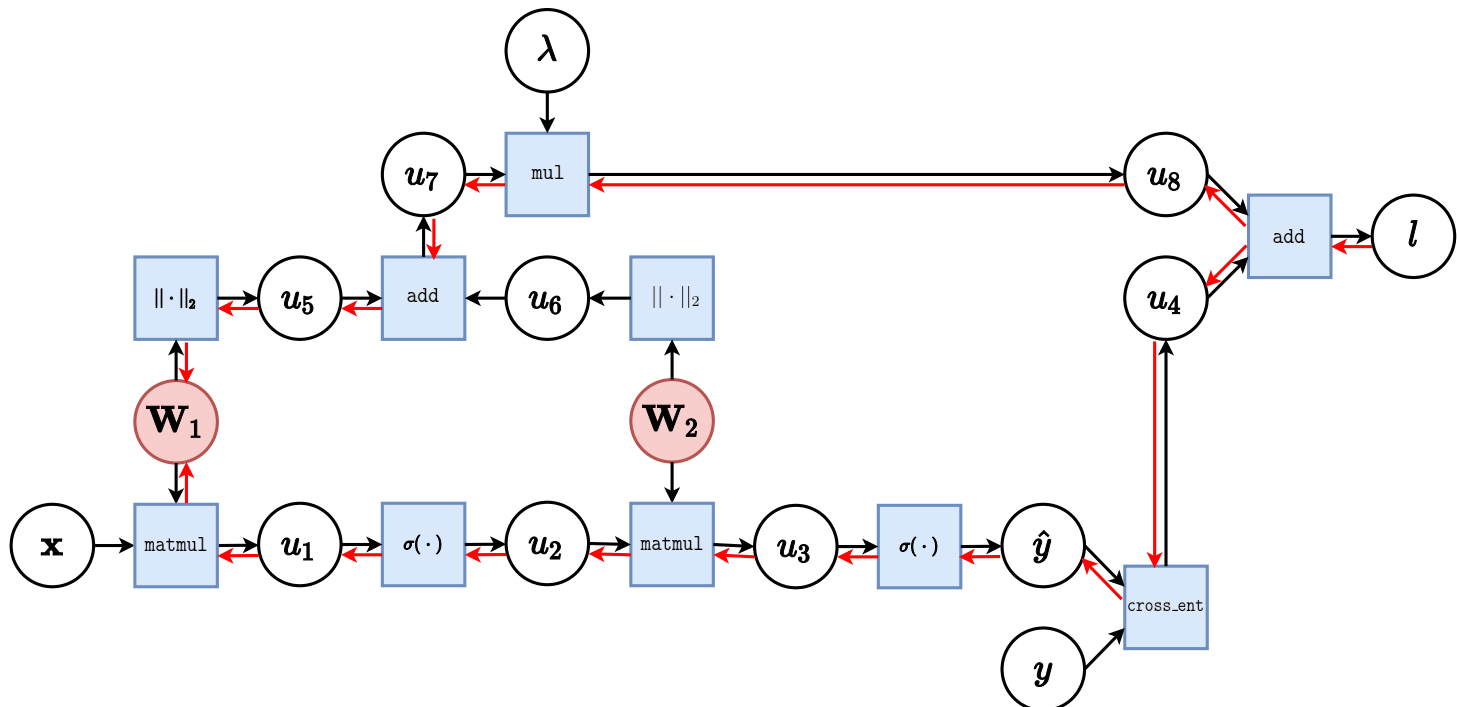

In the **forward pass**, intermediate values are all computed from inputs to outputs, which results in the annotated computational graph below:

The partial derivatives can be computed through a **backward pass**, by walking through all paths from outputs to parameters in the computational graph and accumulating the terms. For example, for  $\frac{\partial l}{\partial \mathbf{W}_1}$  we have:

$$\frac{\partial l}{\partial \mathbf{W}_1} = \frac{\partial l}{\partial u_8} \frac{\partial u_8}{\partial \mathbf{W}_1} + \frac{\partial l}{\partial u_4} \frac{\partial u_4}{\partial \mathbf{W}_1}$$

$$\frac{\partial u_8}{\partial \mathbf{W}_1} = \dots$$

Let us zoom in on the computation of the network output  $\hat{y}$  and of its derivative with respect to  $\mathbf{W}_1$ .

- **Forward pass:** values  $u_1$ ,  $u_2$ ,  $u_3$  and  $\hat{y}$  are computed by traversing the graph from inputs to outputs given  $\mathbf{x}$ ,  $\mathbf{W}_1$  and  $\mathbf{W}_2$ .
- **Backward pass:** by the chain rule we have

$$\begin{aligned} \frac{\partial \hat{y}}{\partial \mathbf{W}_1} &= \frac{\partial \hat{y}}{\partial u_3} \frac{\partial u_3}{\partial u_2} \frac{\partial u_2}{\partial u_1} \frac{\partial u_1}{\partial \mathbf{W}_1} \\ &= \frac{\partial \sigma(u_3)}{\partial u_3} \frac{\partial \mathbf{W}_2^T u_2}{\partial u_2} \frac{\partial \sigma(u_1)}{\partial u_1} \frac{\partial \mathbf{W}_1^T \mathbf{x}}{\partial \mathbf{W}_1} \end{aligned}$$

Note how evaluating the partial derivatives requires the intermediate values computed forward.

# Vanishing gradients

Training deep MLPs with many layers has for long (pre-2011) been very difficult due to the **vanishing gradient** problem.

- Small gradients slow down, and eventually block, stochastic gradient descent.
- This results in a limited capacity of learning.

*Backpropagated gradients normalized histograms (Glorot and Bengio, 2010).  
Gradients for layers far from the output vanish to zero.*

Let us consider a simplified 2-hidden layer MLP, with  $x, w_1, w_2, w_3 \in \mathbb{R}$ , such that

$$f(x; w_1, w_2, w_3) = \sigma(w_3 \sigma(w_2 \sigma(w_1 x))).$$

Under the hood, this would be evaluated as

$$u_1 = w_1 x$$

$$u_2 = \sigma(u_1)$$

$$u_3 = w_2 u_2$$

$$u_4 = \sigma(u_3)$$

$$u_5 = w_3 u_4$$

$$\hat{y} = \sigma(u_5)$$

and its derivative  $\frac{\partial \hat{y}}{\partial w_1}$  as

$$\begin{aligned} \frac{\partial \hat{y}}{\partial w_1} &= \frac{\partial \hat{y}}{\partial u_5} \frac{\partial u_5}{\partial u_4} \frac{\partial u_4}{\partial u_3} \frac{\partial u_3}{\partial u_2} \frac{\partial u_2}{\partial u_1} \frac{\partial u_1}{\partial w_1} \\ &= \frac{\partial \sigma(u_5)}{\partial u_5} w_3 \frac{\partial \sigma(u_3)}{\partial u_3} w_2 \frac{\partial \sigma(u_1)}{\partial u_1} x \end{aligned}$$

The derivative of the sigmoid activation function  $\sigma$  is:

$$\frac{\partial \sigma}{\partial x}(x) = \sigma(x)(1 - \sigma(x))$$

Notice that  $0 \leq \frac{\partial \sigma}{\partial x}(x) \leq \frac{1}{4}$  for all  $x$ .

Assume that weights  $w_1, w_2, w_3$  are initialized randomly from a Gaussian with zero-mean and small variance, such that with high probability  $-1 \leq w_i \leq 1$ .

Then,

$$\frac{\partial \hat{y}}{\partial w_1} = \underbrace{\frac{\partial \sigma(u_5)}{\partial u_5}}_{\leq \frac{1}{4}} \underbrace{w_3}_{\leq 1} \underbrace{\frac{\partial \sigma(u_3)}{\partial u_3}}_{\leq \frac{1}{4}} \underbrace{w_2}_{\leq 1} \underbrace{\frac{\sigma(u_1)}{\partial u_1}}_{\leq \frac{1}{4}} x$$

This implies that the derivative  $\frac{\partial \hat{y}}{\partial w_1}$  exponentially shrinks to zero as the number of layers in the network increases.

Hence the vanishing gradient problem.

- In general, bounded activation functions (sigmoid, tanh, etc) are prone to the vanishing gradient problem.
- Note the importance of a proper initialization scheme.

# Activation functions

Instead of the sigmoid activation function, modern neural networks use the **rectified linear unit** (ReLU) activation function, defined as

$$\text{ReLU}(x) = \max(0, x)$$

Note that the derivative of the ReLU function is

$$\frac{\partial}{\partial x} \text{ReLU}(x) = \begin{cases} 0 & \text{if } x \leq 0 \\ 1 & \text{otherwise} \end{cases}$$

For  $x = 0$ , the derivative is undefined. In practice, it is set to zero.

Therefore,

$$\frac{\partial \hat{y}}{\partial w_1} = \underbrace{\frac{\partial \sigma(u_5)}{\partial u_5}}_{=1} w_3 \underbrace{\frac{\partial \sigma(u_3)}{\partial u_3}}_{=1} w_2 \underbrace{\frac{\partial \sigma(u_1)}{\partial u_1}}_{=1} x$$

This **solves** the vanishing gradient problem, even for deep networks! (provided proper initialization)

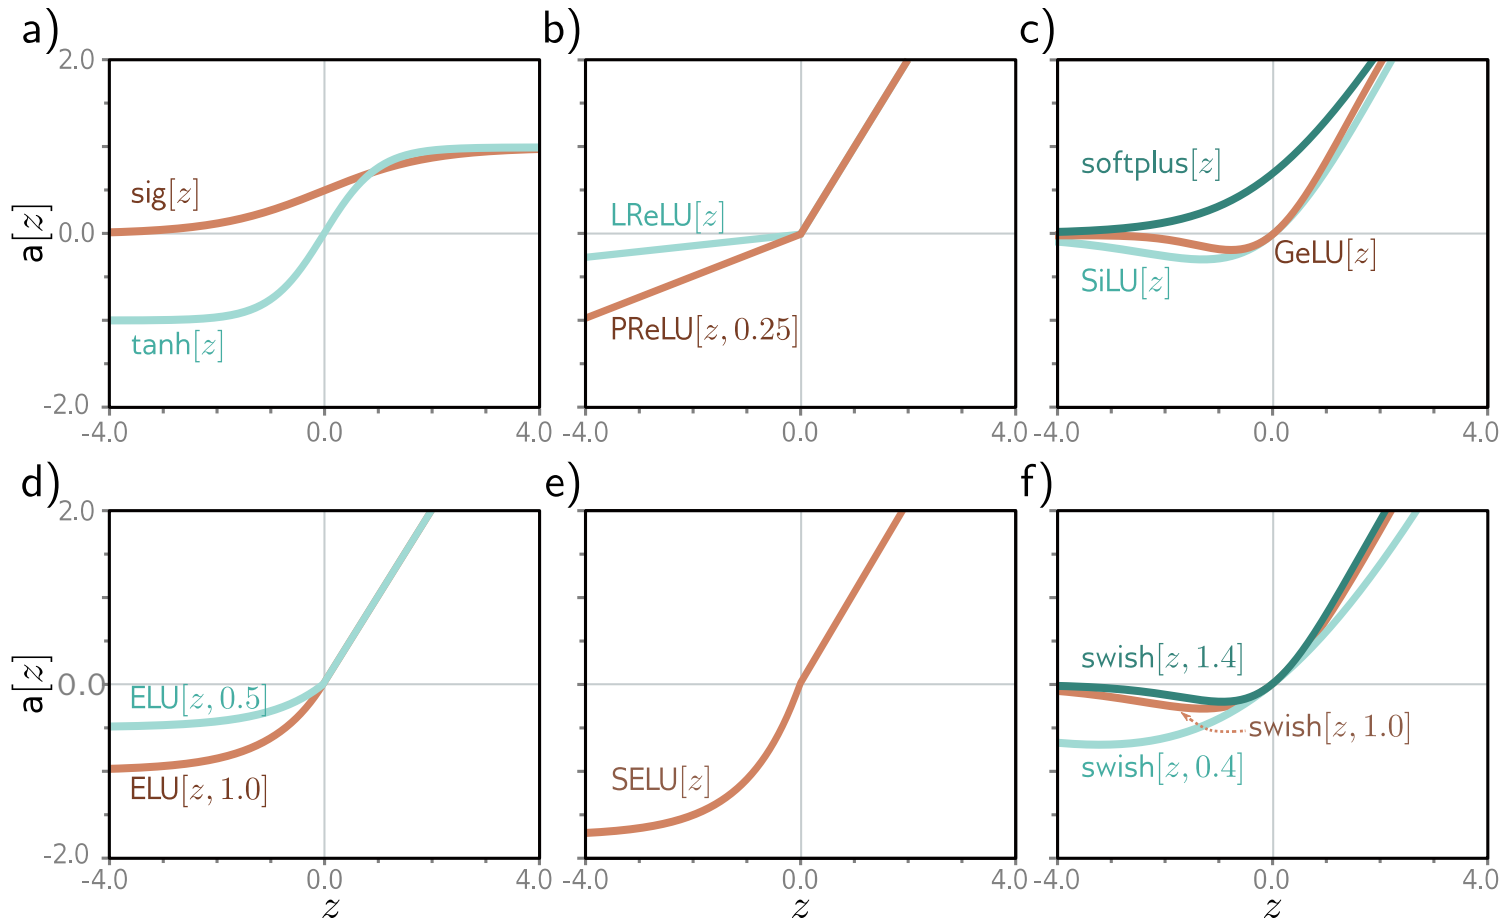

Note that:

- The ReLU unit dies when its input is negative, which might block gradient descent.
- This is actually a useful property to induce **sparsity**.
- This issue can also be solved using **leaky** ReLUs, defined as

$$\text{LeakyReLU}(x) = \max(\alpha x, x)$$

for a small  $\alpha \in \mathbb{R}^+$  (e.g.,  $\alpha = 0.1$ ).

Beyond preventing vanishing gradients, the choice of the activation function  $\sigma$  is critical for the expressiveness of the network.

(demo)

*People are now building a new kind of software by **assembling networks of parameterized functional blocks** and by **training them from examples using some form of gradient-based optimization**.*

Yann LeCun, 2018.
